How to update your website

Step-by-step: daily P&L, a new strategy, backtest data, share codes. Plus how drawdown is calculated.

Your website lives in the GitHub repository **srisuutra/srisuutra.github.io** and shows at **https://srisuutra.github.io/**. The site only *displays* files. You change what it shows by replacing a file in the repository. About one minute after you save, the site shows the new numbers (press Ctrl+F5 to refresh).

What each file does

What you want to change	File on GitHub	Made by
Daily P&L (Daily PnL Report tab)	**live/data.json**	Daily tool, button *Export website data (data.json)*
Backtest results (Backtest, Trade tabs)	**reports/<name>.json** and **reports/index.json**	Backtest tool, then *prepare_report.html*
Strategies tab (link and share code)	**share-codes.json** (top folder)	*strategies_editor.html*
Telegram link	**config.json**	edit on GitHub (pencil icon)

Your three helper pages (in the local folder of the repository; double-click to open in Chrome). Each can publish straight to GitHub after a one-time connection (next page):

daily_entry.html (daily P&L, Excel, Telegram post) | **strategies_editor.html** (strategy links and share codes) | **prepare_report.html** (backtest file for the website)

How to upload a file to GitHub by hand (fallback if you do not use the publish buttons)

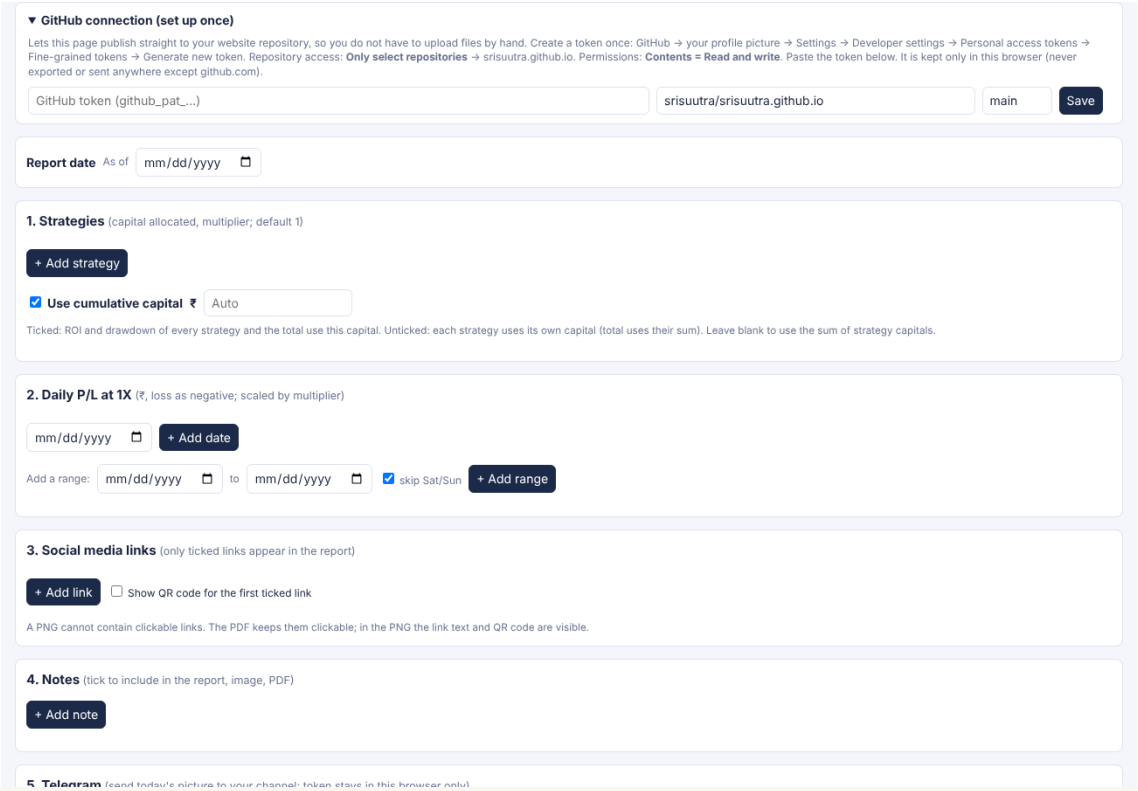

1. Open **https://github.com/srisuutra/srisuutra.github.io** and sign in.
2. Open the folder where the file belongs (for example **live**). For files in the top folder, stay on the front page.
3. Click **Add file** (green/grey button, top right) and then **Upload files**.
4. Drag your file into the box. **The file name must be exactly the same as the old one** (for example **data.json**); a file with the same name replaces the old one.
5. Scroll down, type a short message (for example *Update 2 Nov*) and click the green **Commit changes** button.
6. Wait about one minute, open the website and press **Ctrl+F5**. Look at the grey line at the very bottom of the site: it must say *live data: loaded (N days)* and *reports found: 1*.

Alternative: if you prefer GitHub Desktop, copy the file into the cloned **srisuutra.github.io** folder (same sub-folder), then in GitHub Desktop click **Commit to main** and **Push origin**. Always click **Fetch origin** first so your copy is up to date.

One-time setup: connect the tools to GitHub

After this, every tool has a **Publish to GitHub** button. One click replaces the file in your repository and the website updates in about a minute. You do this once per browser.

1. Sign in to GitHub. Click your profile picture (top right), then **Settings**, then **Developer settings** (bottom of the left menu), then **Personal access tokens**, then **Fine-grained tokens**, then **Generate new token**.
2. Name: **SRISUUTRA website**. Expiration: choose 1 year (GitHub emails you before it ends; make a new one then).
3. **Repository access**: choose **Only select repositories** and pick **srisuutra.github.io**. Under **Repository permissions** set **Contents** to **Read and write**. Click **Generate token** and copy it (starts with github_pat_). You cannot see it again.
4. Open any tool (daily_entry.html, strategies_editor.html or prepare_report.html). In the **GitHub connection** box at the top paste the token and click **Save**. Repository is **srisuutra/srisuutra.github.io**, branch **main**.

The token is stored only in that browser on that computer (never inside the Excel, data.json or any file) and is sent only to github.com. Treat it like a password; if you lose a computer, delete the token in GitHub settings. If a publish says *refused (401/403)*, the token expired or lacks Contents: Read and write.

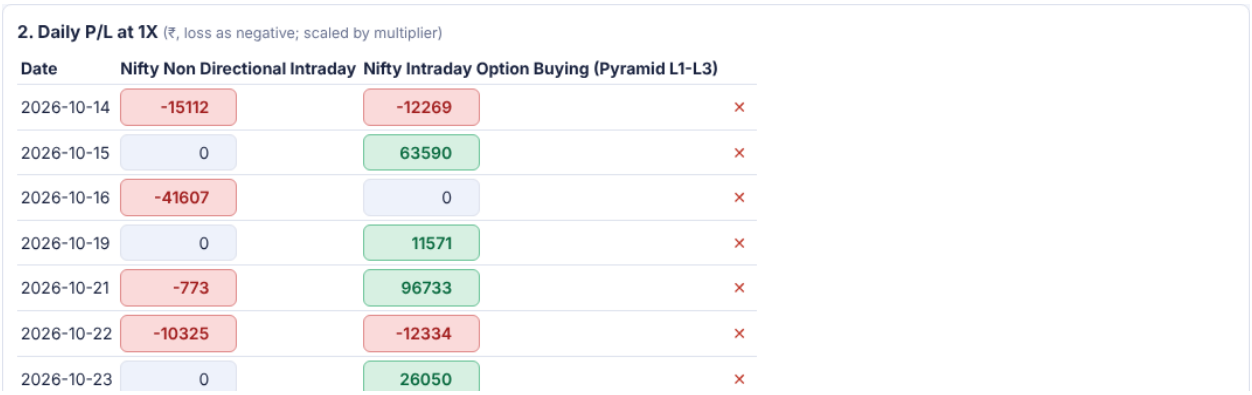

A. Update the daily P&L

Do this after market close, every trading day (about 2 minutes).

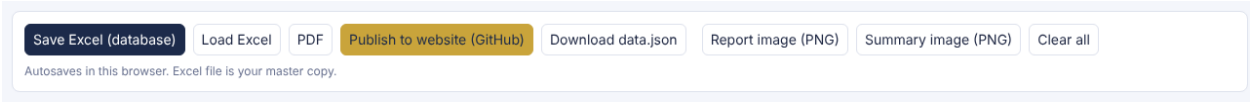

1. Open **local/daily_entry.html** in Chrome. The first time on a computer, click **Load Excel** (bottom button row) and choose your master file **SRISUUTRA_ALGO_database.xlsx**. After that the page remembers your data in that browser.
2. Top of the page: set **As of** to today's date.

3. In section 2, pick today's date in the box under the table and click **+ Add date**. A new row appears. (To fill many days at once use **Add a range**: choose start and end date and click **+ Add range**; weekends are skipped.)

4. Type each strategy's **net P&L for the day** as your broker shows it (charges already deducted). Losses with a minus sign, e.g. **-15112**. Type **0** if the strategy did not trade. The box turns green for profit, red for loss.
5. Check the report shown further down the page (Today, Month, YTD, drawdown). If today's numbers look wrong, fix the row; everything recalculates.
6. Scroll to the button row. Click **Save Excel (database)**: this downloads your master Excel. Keep it in a safe folder **outside** the website folder. Then click the gold **Publish to website (GitHub)**. When it says *Published*, you are done (the site updates in about a minute).

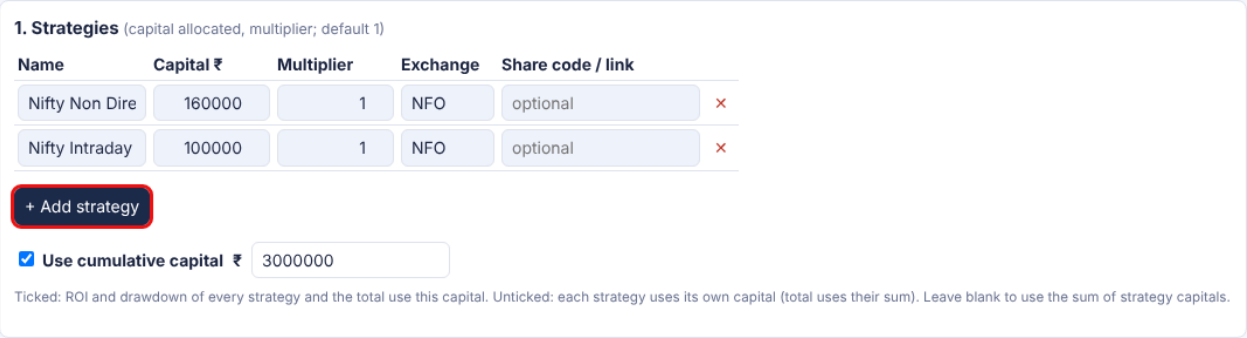

7. No token yet? Click **Download data.json** and upload it to the **live** folder by hand (page 1). Same name = it replaces yesterday's file.

Optional, Telegram post: in section 5 of the same page enter your bot token and channel once, then click **Send summary picture to Telegram** to post today's picture and numbers. It is separate from the website upload.

Never edit a past day by accident: the website shows exactly what is in data.json. If you correct an old day, export and upload again.

B. Add a new strategy and its P&L

1. Open **local/daily_entry.html**. In section 1 click **+ Add strategy**.

2. Fill in the new row: **Name** (as you want it shown), **Capital** (rupees allotted to it), **Multiplier** (1 unless you trade it larger), **Exchange** (**NFO** or **MCX**). Leave **Share code** empty for now.
3. Capital for ROI and drawdown: if **Use cumulative capital** is ticked, all percentages use the amount in the rupee box (currently the total). Update that total to include the new strategy's capital, or clear the box to use the sum of all strategy capitals. **This changes the ROI and drawdown percentages of the whole history**, because they are measured on that capital.
4. In section 2 a new column appears with the new strategy's name. Type its P&L for every date it has traded. **Leave the cell empty for dates before it started** (empty = not running; 0 = ran but made nothing).
5. Save Excel, click **Publish to website (GitHub)**, exactly as in section A.
6. To list the new strategy on the **Strategies** tab as well, follow section D (add the name, link and code there).

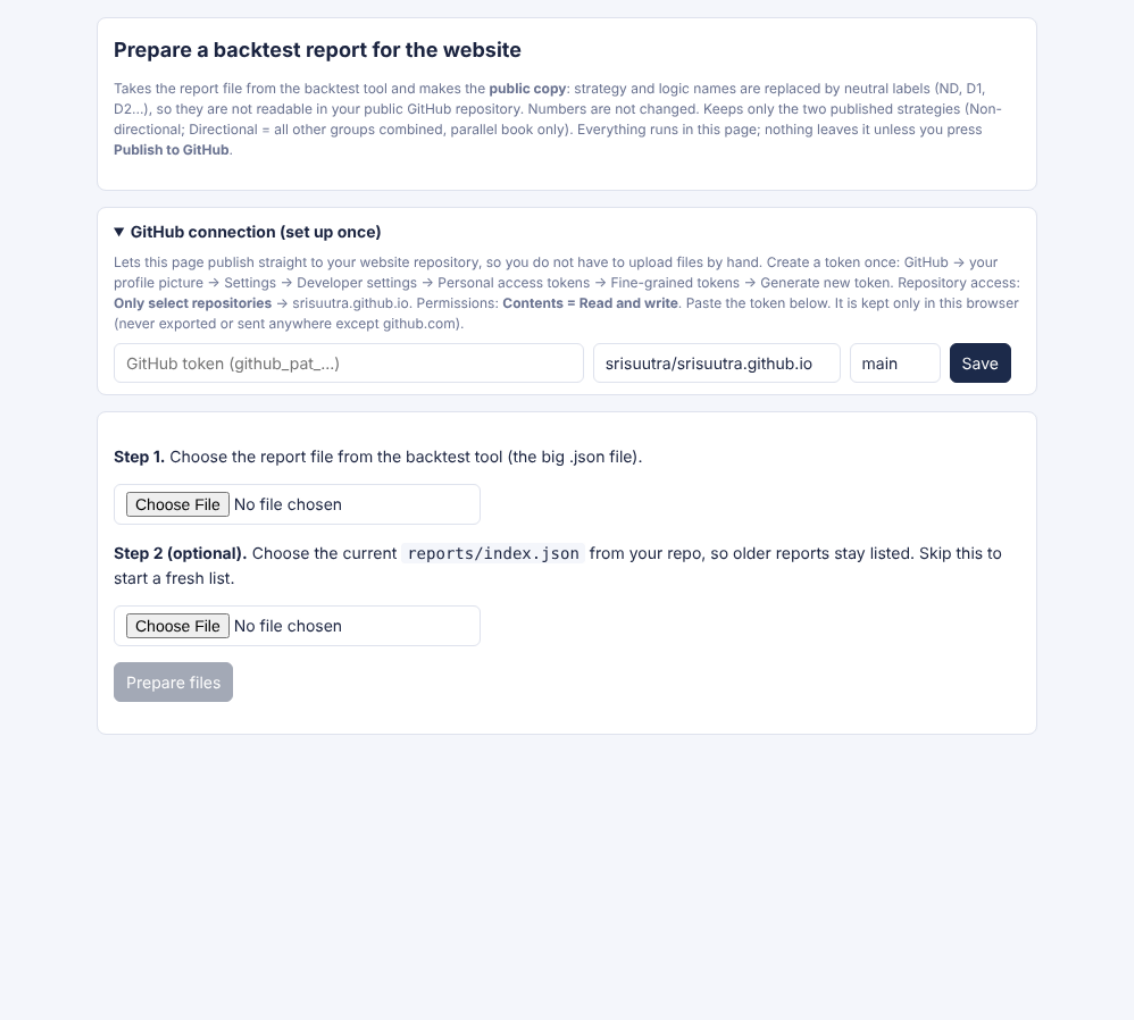

Right now there are **two strategies**: Nifty Non Directional Intraday and Nifty Intraday Option Buying (Pyramid L1-L3). The daily tool opens with the data currently on the website, so you can add today and publish straight away. If you load an old Excel that still has separate Bullish and Bearish columns, the tool combines them into the Option Buying strategy automatically.

To **stop** a strategy: keep its history, simply stop entering new days (leave cells empty). Deleting it with the red **x** in section 1 also deletes its P&L history.

C. Replace the backtest data

Do this whenever you run a new backtest. Names of your strategies and logics must not appear in the public repository, so the report goes through a small clean-up page first. It publishes two strategies only: **Nifty Non Directional Intraday** and **Nifty Intraday Option Buying (Pyramid L1-L3)** (all other logics combined, parallel book only). Capital comes from the report itself. Totals are recalculated from what remains.

1. Run your backtest tool and export the report. You get one large **.json** file named like **combined_parallel_2021-08-02_2026-09-22.json**.
2. Open **local/prepare_report.html**. **Step 1:** choose that large file. **Step 2 (optional):** choose the current **reports/index.json** if you want older reports to stay listed (to replace the old report completely, skip step 2). Click **Prepare files**.

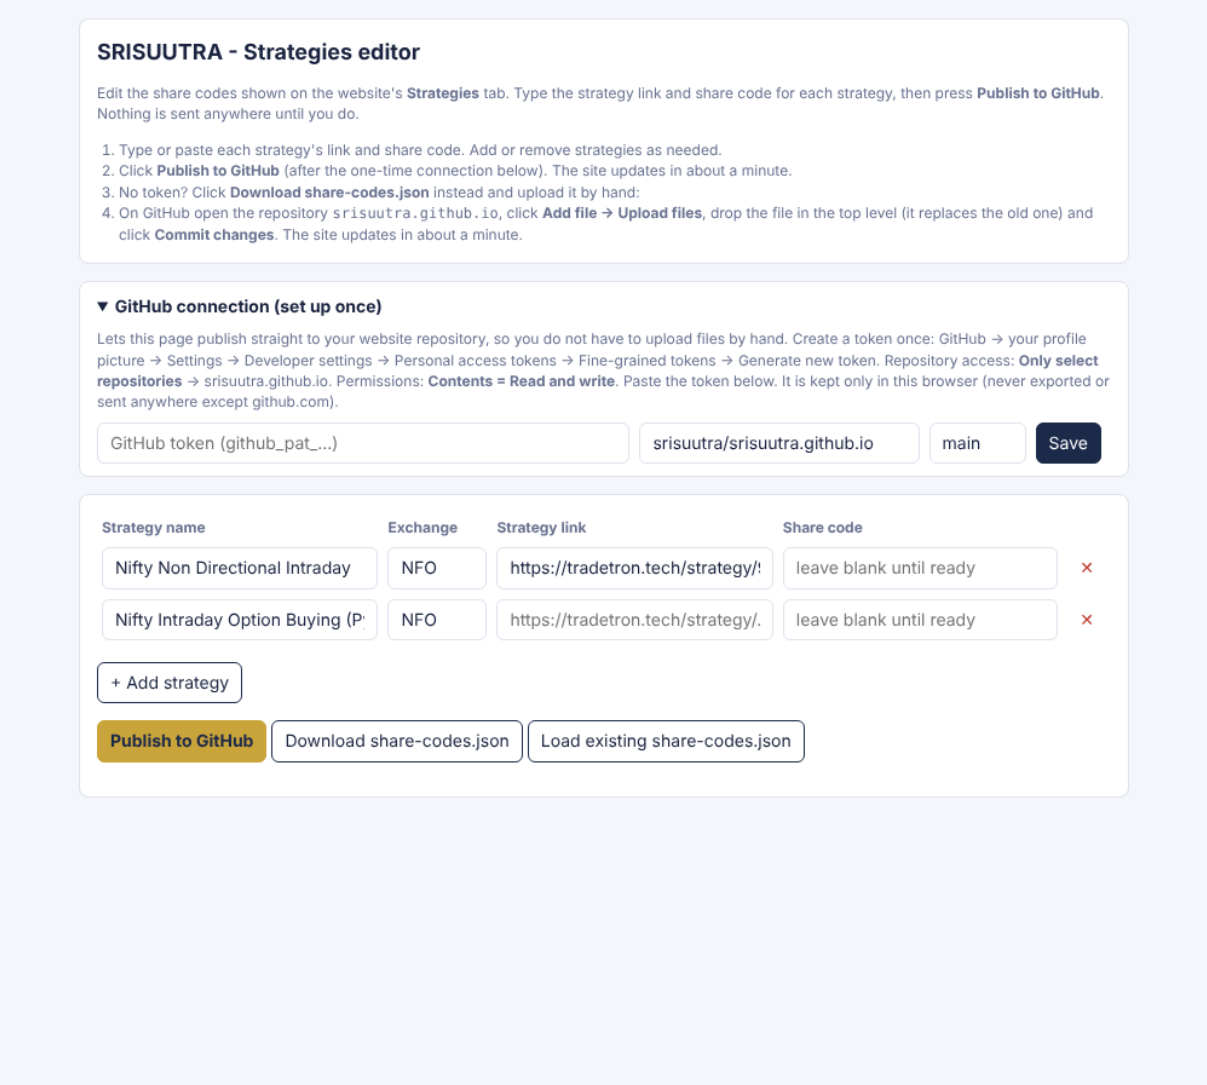

3. The page shows what it did (names replaced, only parallel legs kept) and offers **Publish to GitHub now**, which uploads the cleaned report and **index.json** into the **reports** folder. No token? Use the two download buttons and upload both files by hand.
4. Publishing replaces **index.json** (the list of reports) and adds the new report file next to the others.
5. Old report files that are no longer listed in index.json are not shown; you can leave them or delete them (open the file on GitHub, click the three dots, **Delete file**, commit).
6. Check the website: **Backtest Analysis** tab. The Net P&L, ROI and max drawdown at the top must equal the numbers of your backtest tool. The footer must say *reports found: 1* (or more).

Several reports at once: run the clean-up page once per report. For the second report use **Step 2** with the **index.json** you downloaded last time, so the list keeps growing.

Do not upload the raw report from the backtest tool directly: it contains your internal strategy and logic names, and the repository is public.

D. Update strategy links and share codes (Strategies tab)

1. Open **local/strategies_editor.html** in Chrome. It starts with the two strategies. First time on a computer you can click **Load existing share-codes.json** and choose the current file (download it from GitHub: open the file, click the download icon).

2. Type or paste the **Strategy link** and the **Share code** of each strategy. Set **Exchange** (NFO / MCX). A blank link or code shows "Not published yet" on the site.
3. New strategy: click **+ Add strategy**, type its name, exchange and code. Remove one with the red **x**.
4. Click **Publish to GitHub**. (No token? Click **Download share-codes.json** and upload it by hand.)
5. By hand only: upload **share-codes.json** to the **top folder** of the repository (not inside any sub-folder), replacing the old file.
6. Open the website, **Strategies** tab, press Ctrl+F5. Each strategy has an **Open strategy** link and a share code with a **Copy** button.

Quick edit alternative: on GitHub open **share-codes.json**, click the **pencil** icon, type the code between the quotes after **"code":**, and click **Commit changes**.

Telegram link: the **Telegram** button at the top right of every page uses **config.json** (**"telegram": "https://t.me/SRISUUTRA_ALGO_TRADING"**). To change it, edit that file on GitHub with the pencil icon.

If something does not show: read the grey line at the bottom of the website

Footer says	Meaning / fix

live data: not found	No **live/data.json** on GitHub. Upload the file into the **live** folder with the exact name **data.json**.
reports found: 0	**reports/index.json** is empty or the report file is missing. Repeat section C.
It lists "Data files found in the repository"	The file is in the wrong folder or has the wrong name (Windows often hides ".txt" after ".json"). Rename it and upload again.
Old numbers after upload	Wait one minute and press Ctrl+F5.

E. How drawdown is calculated

Drawdown is how far the account has fallen from its best point so far. There are two slightly different presentations on the website, because they follow the two tools they come from.

Backtest tabs (Backtest Analysis, Trade Analytics)

1. Build the running total of net P&L day by day, starting at zero (**cumulative P&L**, after costs).
2. The **peak** is the highest cumulative P&L reached so far (the start counts as zero).
3. Drawdown in rupees on any day = **peak minus today's cumulative P&L**. Max drawdown is the biggest such value in the whole period.
4. Drawdown in percent = **drawdown rupees divided by the capital chosen on the Capital slider** (the starting capital), not divided by the equity peak.

> Example: the combined portfolio's deepest fall from a peak was Rs 49,706. Capital deployed (from the report) is Rs 2,00,000. 49,706 / 2,00,000 = **24.85%**. If a single group is selected it is measured on its own capital, so a group that fell by more than its own capital would show over 100%.

Move the Capital slider and the percentage changes (same rupees, bigger base). Drawdown uses daily closing P&L; a dip inside a day that recovers by the close is not counted. For a one-trade-per-day style the figures are per day; reports that say "trade basis" measure each trade.

Daily PnL Report tab (live results)

This follows the formula of your daily tool: equity = **capital + cumulative P&L**; the peak is the highest equity so far; drawdown in percent = **fall from that peak divided by the peak equity**. The capital is the cumulative capital in the tool (Rs 30,00,000 now). Because the base is the peak equity (capital plus profit so far), the percentage is a little smaller than a division by the starting capital would give once the account has grown.

> Both are valid; they simply use a different base (starting capital versus peak equity). Backtest numbers should therefore not be compared digit-for-digit with the live numbers. If you prefer one method everywhere, tell your developer and both pages can be switched to it.
